STAT 210

Applied Statistics and Data Analysis Problem List 9 (Due on Week 10)

Exercise 1

In this exercise we re-visit exercise 1 from last week. Then, we extracted the data corresponding to species 'setosa' from the iris data set and considered a simple linear regression of Sepal.Width on Sepal.Length. We reproduce below the summary table for this regression.

```
iris.set <- subset(iris, Species == 'setosa')</pre>
modelA <- lm(Sepal.Width ~ Sepal.Length, data = iris.set)</pre>
summary(modelA)
##
## Call:
## lm(formula = Sepal.Width ~ Sepal.Length, data = iris.set)
##
## Residuals:

```

We see that the intercept is marginally significant, and in this case, where we are dealing with a physical model, it makes sense that the intercept be equal to zero. The purpose of this exercise is to fit a model with intercept equal to zero and compare with the previous model.

(i) Fit a model of Sepal.Width as a function of Sepal.Length, with intercept equal to zero. To do this, add a term -1 to the regression equation. Produce the summary table and compare the estimated value for the regression slope with the previous result. Compare also the standard error for both estimates and the R² for both models. Look also at the correlation matrix for the two parameters in the model including the intercept (to do this, set corr = TRUE in the call to summary.)

```
modelB <- lm(Sepal.Width ~ -1 + Sepal.Length, data = iris.set)
summary(modelB)</pre>
```

```

```

We now want to compare the predictive power for each type of model in this particular example. For this, we are going to use the idea behind leave-one-out cross-validation. We select one data point from the set, let's say it is the i-th one, and we fit both regression models with the remaining 49 points. With this model, we predict the value for the i-th point and now we can compare with the observed value.

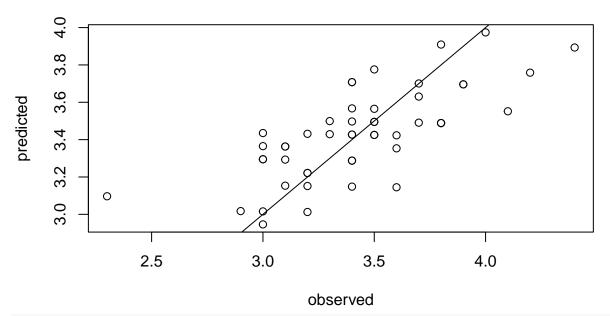

(iii) Implement the procedure described above for all fifty points in iris.vir. Produce a matrix with three columns, the first column (P1) should have the predicted value with the model including an intercept, the second column (P2) corresponds to the predicted value for the model without the intercept, and the third column (0) should be the observed value.

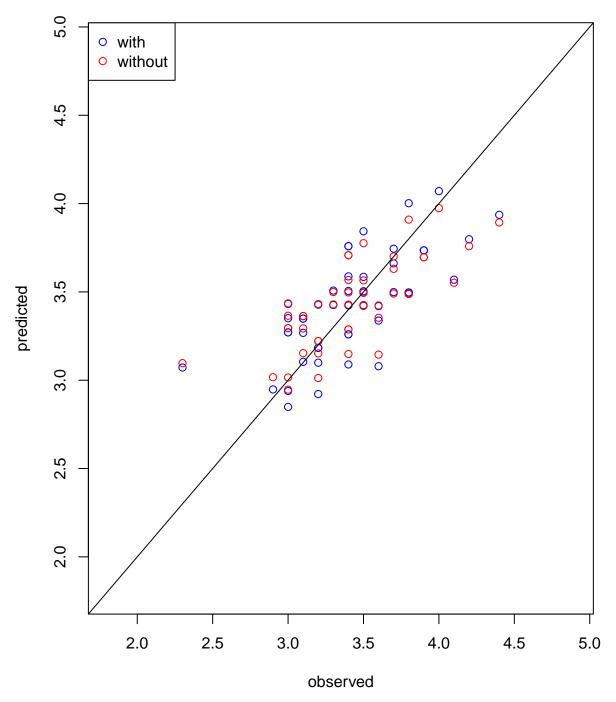

```
attach(iris.set)
pred.values <- matrix(rep(0,100), ncol = 2)</pre>
for (i in 1:50) {
  xx <- Sepal.Length[-i]
  yy <- Sepal.Width[-i]</pre>
  model1 \leftarrow lm(yy \sim xx)
  model2 \leftarrow lm(yy \sim -1 + xx)
  pred.values[i,1] = predict(model1, data.frame(xx = Sepal.Length[i]))
  pred.values[i,2] = predict(model2, data.frame(xx = Sepal.Length[i]))
pred.values <- cbind(pred.values,Sepal.Width)</pre>
colnames(pred.values) <- c('P1', 'P2', '0')</pre>
str(pred.values)
   num [1:50, 1:3] 3.5 3.35 3.18 3.1 3.42 ...
##
   - attr(*, "dimnames")=List of 2
     ..$: NULL
##
     ..$ : chr [1:3] "P1" "P2" "0"
head(pred.values)

## [1] 0.2079689

mean(abs(pred.values[,2]-pred.values[,3]))

## [1] 0.2005491
```

Exercise 2

The data for this question is stored in the file data("diamond") in package HH. The dataset presents data on the price (Singapore dollars) of ladies' diamond rings and the number of carats in the ring's diamond. The data are accessed as data(diamond).

```
library(HH)
data(diamond)
```

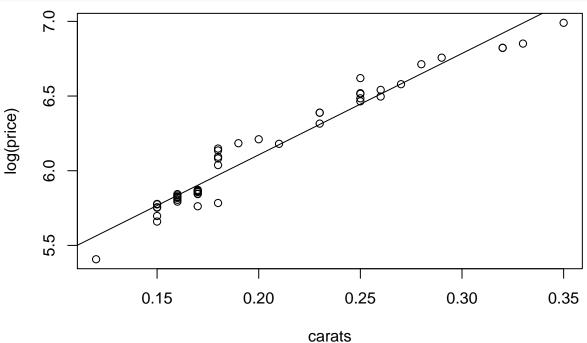

```
str(diamond)
```

```
## 'data.frame': 48 obs. of 2 variables:
## $ carats: num   0.17 0.16 0.17 0.18 0.25 0.16 0.15 0.19 0.21 0.15 ...
## $ price : int   355 328 350 325 642 342 322 485 483 323 ...
```

(a) Regress the logarithm of price on carats. Do a scatterplot of these variables and include the regression line. Interpret the slope of the regression line. Write down an equation for price according to this model

```
mod1 <- lm(log(price) ~ carats, data = diamond)
summary(mod1)</pre>
```

```
##
## Call:
## lm(formula = log(price) ~ carats, data = diamond)
##
## Residuals:
##
                    1Q
                          Median
                                         3Q
  -0.186792 -0.044812 -0.005545 0.064524
                                            0.177851
##
## Coefficients:
##
               Estimate Std. Error t value Pr(>|t|)
                4.74891
                           0.04775
                                     99.46
                                              <2e-16 ***
## (Intercept)
## carats
                6.78725
                           0.22547
                                     30.10
                                              <2e-16 ***

##
## Residual standard error: 0.08778 on 46 degrees of freedom
## Multiple R-squared: 0.9517, Adjusted R-squared: 0.9506
## F-statistic: 906.2 on 1 and 46 DF, p-value: < 2.2e-16
plot(log(price) ~ carats, data = diamond)
abline(mod1)
```

The slope is the rate of increase of the logarithm of the price of diamonds (in Singapure dollars) per unit increase in carat. The equation is

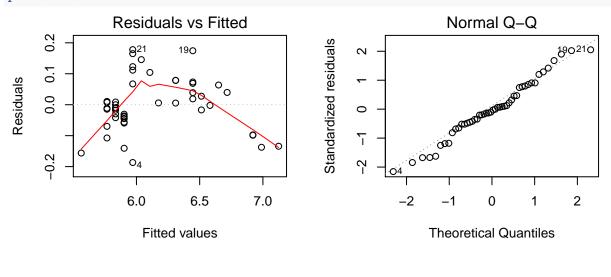

$$\log(\text{price}) = 4.749 + 6.787 * \text{carats}$$

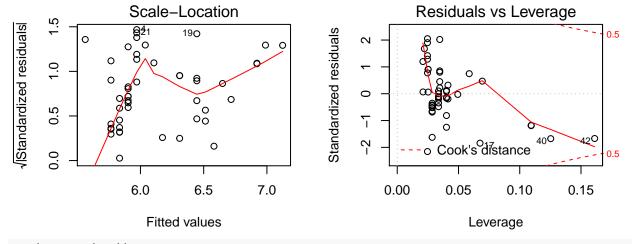

and in Singapore dolars

$$price = exp(4.749 + 6.787 * carats) = 115.46 * exp(6.787 * carats)$$

(b) Do residual plots and discuss the results.

par(mfrow=c(2,2))
plot(mod1)

par(mfrow=c(1,1))

The quantile plot has a good fit to the normal distribution but the other plots do not look good, residuals against fitted values shows unequal dispersion and more positive values at the center while the scale location plot shows an increasing tendency in dispersion.

A useful tool is the function residual Plots in the car package. This function plots residuals against all the regressors and also against fitted values, and adds a quadratic term. It also tests the significance of the added term and lists the p-values. In thie case, the quadratic term for car ats has a small p-value.

residualPlots(mod1, type = 'rstandard') 8 8 \sim \sim 0 0 0 8 8 0 Rstandard residuals Rstandard residuals 0 0 0 0 0 0 0 0 0 0 T 7 0 0 0 0 О 7 0 0 0.15 0.25 0.35 6.0 6.5 7.0

```

In the new model, all terms are significant. The R^2 has increased form 0.9517 to 0.9712. To calculate the AIC we use the function stepAIC

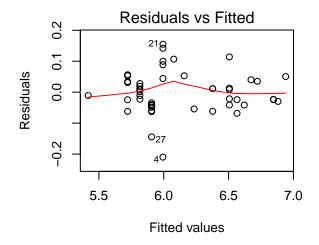

```
library(MASS)
stepAIC(mod2)
```

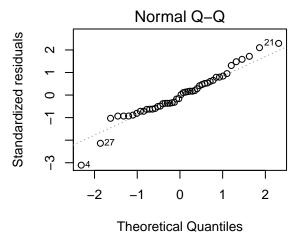

```
## Start: AIC=-254.43
## log(price) ~ carats + I(carats^2)
##
##
                 Df Sum of Sq
                                  RSS
                                           AIC
## <none>
                              0.21129 -254.43
## - I(carats^2)
                      0.14314 0.35444 -231.60
                 1
## - carats
                  1
                      0.47811 0.68940 -199.67
##
## Call:
## lm(formula = log(price) ~ carats + I(carats^2), data = diamond)
##
## Coefficients:
## (Intercept)
                     carats I(carats^2)
         3.887
                     14.860
                                 -17.537
```

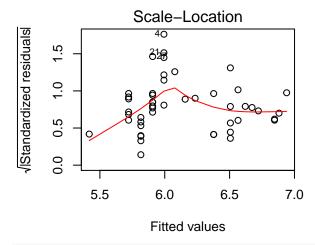

The first model has an AIC of -231.6, and adding the quadratic term has reduced it to -254.43.

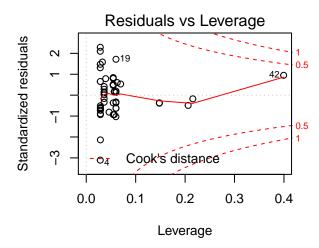

We plot the diagnostic graphs

```
par(mfrow=c(2,2))
plot(mod2)
```

par(mfrow=c(1,1))

All the plots have improved considerably.

The equation for this model is

$$\log(\text{price}) = 3.887 + 14.89 * \text{carats} - 17.54 * \text{carats}^2$$

and in Singapore dollars

$$\texttt{price} = \exp(3.887 + 14.89 * \texttt{carats} - 17.54 * \texttt{carats}^2) = 48.77 * \exp(14.89 * \texttt{carats} - 17.54 * \texttt{carats}^2)$$

(d) Which model would you choose and why?

The second model. It has higher \mathbb{R}^2 , smaller AIC and the diagnostic plots are better.

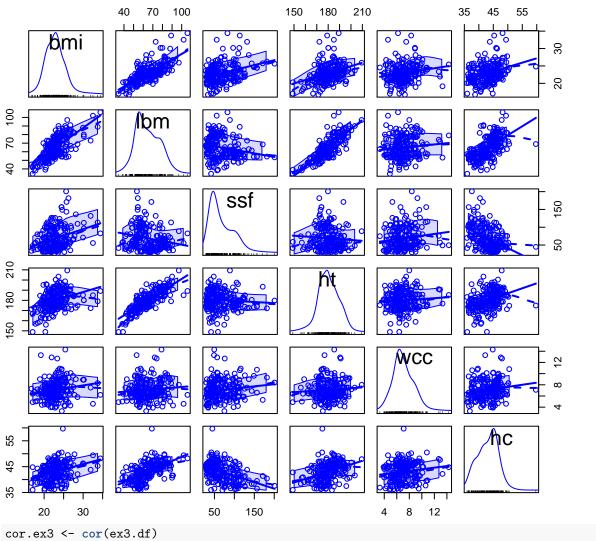

Exercise 3

For this exercise we use the data set ais in library DAAG. We concentrate in six variables, bmi, lbm, ssf, ht, wcc, and hc.

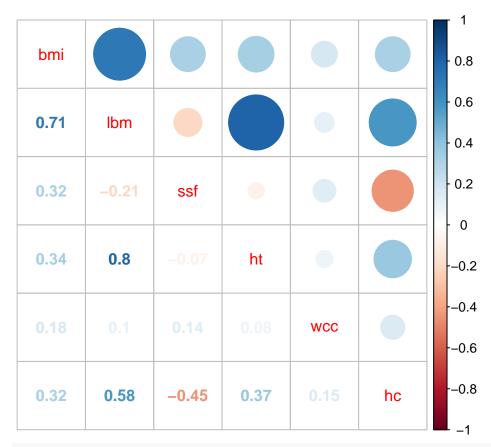

```
library(DAAG)
data(ais)
str(ais)
                    202 obs. of 13 variables:

##
      40.60659
                     0.32189
                                   0.05096
                                               -0.23798
                                                              0.01879
```

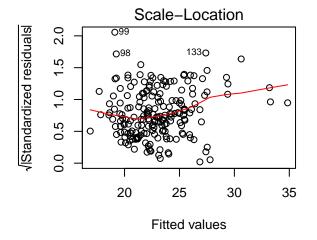

Both AIC and R^2 choose the second model, lm2. Observe, however, that the change in adjusted R^2 is 0.9692 to 0.969, and the difference in AIC is -272.86 to -272.8, a very small difference in both cases. I would keep the simpler model lm3.

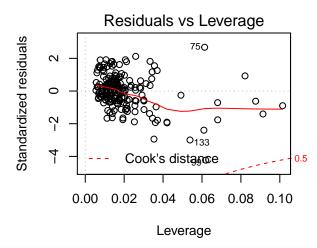

(v) Draw the diagnostic plots for your final model and discuss them

```
par(mfrow=c(2,2))
plot(lm3)
```

par(mfrow=c(1,1))

The quantile plot has departures from the straight line at the lower end and the scale-location plots shows an increasing pattern. We use tests for normality and homoscedasticity

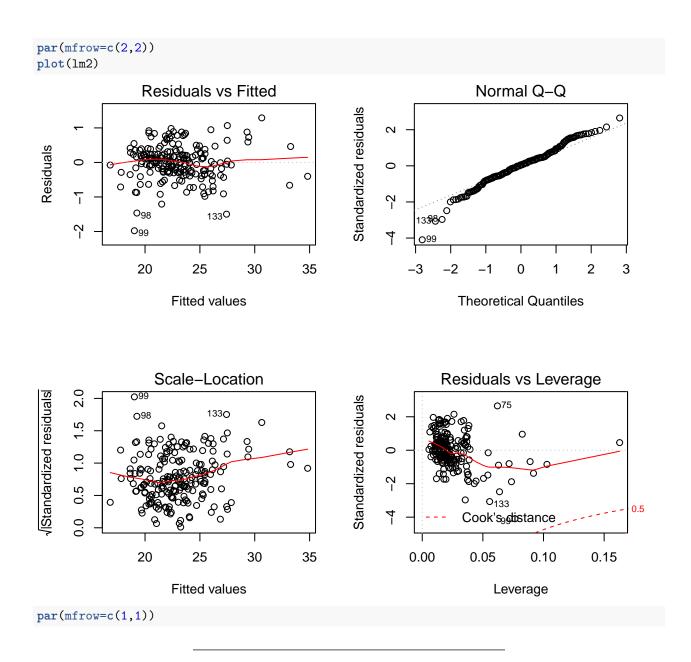

shapiro.test(rstandard(lm3))

```
##
## Shapiro-Wilk normality test
##
## data: rstandard(lm3)
## W = 0.97783, p-value = 0.002773
ncvTest(lm3)
## Non-constant Variance Score Test
```

Non-constant Variance Score Test
Variance formula: ~ fitted.values
Chisquare = 2.172076, Df = 1, p = 0.14054

The normality test rejects the null hypothesis of a normal distribution, but the homoscedasticity assumption is not rejected.

For comparison, we plot the diagnostic graphs for the other model. The differences are small.

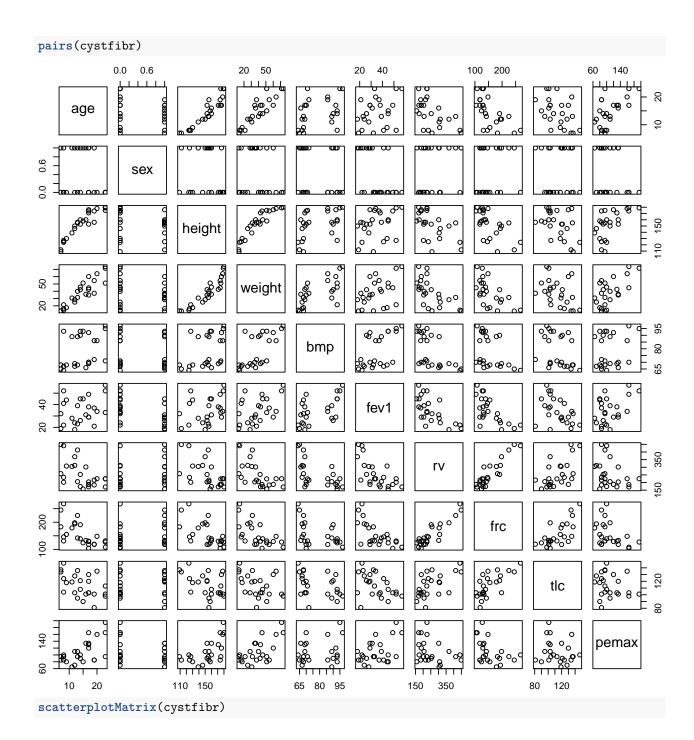

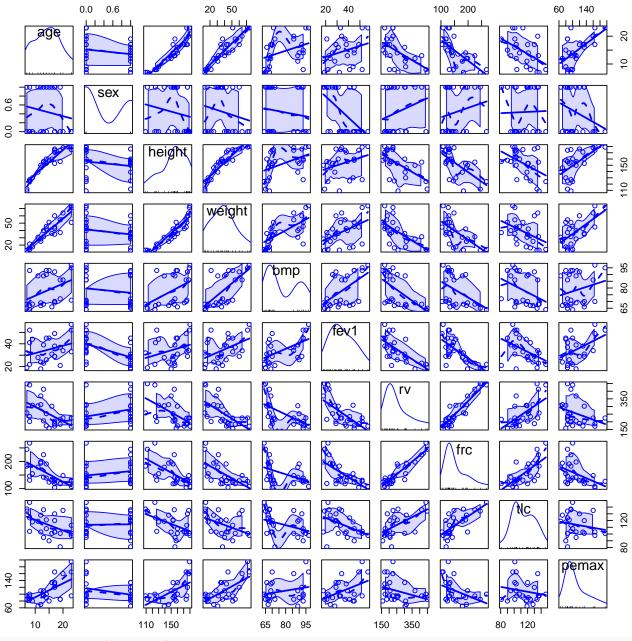

Exercise 4

For this exercise we use the data set cystfibr in the package ISwR.

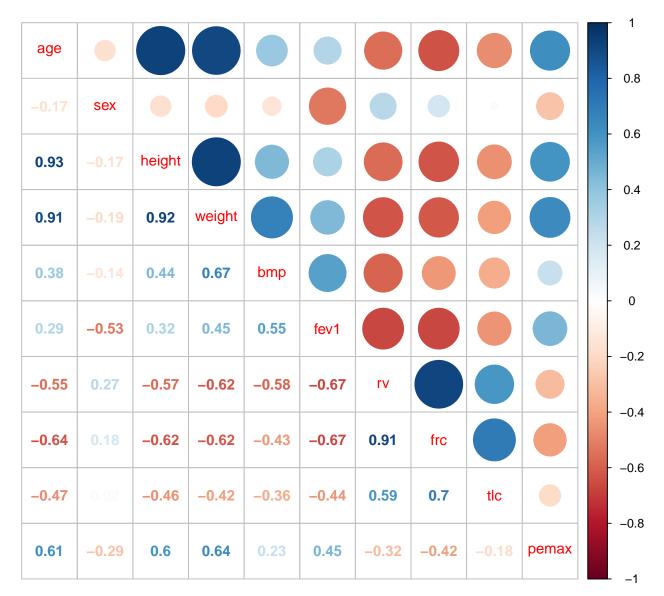

```
library(ISwR)
library(corrplot)
data(cystfibr)
```

(i) Use the help to get familiar with the information contained in this set. Plot a graph matrix of the variables in the set. Use corrplot.mixed to get a correlation matrix graph.

cor.ex4 <- cor(cystfibr)
corrplot.mixed(cor.ex4)</pre>

(ii) Fit a model of pemax as a function of the remaining variables. Place age as the first terms in the regression equation (pemax ~ age + ...). Obtain a summary table and use anova to get an anova table for the regression. Observe that the tests are not the same in both tables. (This will be explained in class).

```
model1 <- lm(pemax ~ ., data = cystfibr)
summary(model1)</pre>
```

```
##
## Call:
## lm(formula = pemax ~ ., data = cystfibr)
##
